Editor-in-Chief
Journal of Cheminformatics

Dear Editor-in-Chief,

Please consider the methodology article ***Exact canonicalization of configured molecular stereographs***. It addresses molecular identity when local configurations coexist with whole-molecule symmetry, extended stereochemical supports, and incomplete information. The manuscript separates configured identity from carrier perception, derived nomenclature, and experimental configurational stability.

Ordered local frames, stereo-aware canonicalization, and rotation-based coordination comparison are established by MØD, Molassembler, RDKit, MACE, and StereoMolGraph. Our advance is a uniform faithful reduction of a declared catalogue of configured supports to a colored auxiliary graph, with explicit transport, mirror, identity-profile, and information contracts. The construction preserves and reflects stereo-isomorphism; full canonical certificates then decide identity and mirror relations. Unresolved strict inputs and computations that exceed their declared bounds refuse a definitive result.

Validation uses an independent assignment-partition oracle on 63 fixtures and 2439 assignments, including simultaneous and coupled configurations. All 7 deliberate implementation defects are rejected. Newly sourced coordination examples are annotated geometrically before production evaluation: 38 of 40 satisfy the frozen fit criteria, and every certified source/mirror and renumbering comparison agrees. The 2 geometry refusals remain in the selected denominator. A separate set of 48 sourced constitutional negatives and a frozen, source-assisted review of 60 development-corpus structural loci support explicitly bounded perception claims. These studies do not establish experimental persistence. Controlled runtime and memory measurements include resource-censored outcomes; a registration example recovers independently specified groups but shows no speed advantage for certificate grouping.

The article fits the journal's methodology scope through its representation, proof, implementation, and reproducible evaluation. Machine-readable reports, input checksums, independent fixtures, and maintained experiment runners accompany the revision. The molecular identity result is self-contained; reaction-rule transport lies outside the article's validation scope.

Sincerely,
Tieu-Long Phan
